

What are non-manifold solids in Boolean operations?

For Surface bodies, each interior edge connects to two faces, and each boundary edge connects to exactly one face. Most often, non-manifold solids can occur during Enclosure operations, where bodies touch at an edge or vertex. For Surface bodies, any type of 'T' intersection is considered non-manifold and is not permitted in Boolean operations.

Does Ansys designmodeler require a manifold?

All solid and surface geometry created in the Ansys DesignModeler application must be manifold. This means that for Solid bodies, each edge connects to exactly two faces. For Surface bodies, each interior edge connects to two faces, and each boundary edge connects to exactly one face.

Why is a solid a manifold?

This solid is invalid because the top edge connects to four faces instead of two. When split into two bodies, this geometry becomes manifold. This surface body is invalid because it contains a 'T' intersection. The middle edge is connected to three faces. When kept separate, two bodies remain manifold.

Ansys Workbench Ansys Fluent, Fluent Ansys CFX:CFX Abaqus nCode DesignLife, ...

When creating the boundary layer, the message "Cannot handle a dangling non-manifold face zone" may be displayed. If the skew is not a problem, then it is hard to find the ...
